### Introduction to Scikit-Learn: Machine Learning with Python

Classification

Tony Yao-Jen Kuo

### **About supervised learning** In Supervised Learning, we have a dataset consisting of both features and labels. The task is to construct an estimator which is able to predict the label of an object given the set of features.

### Some more complicated examples are:

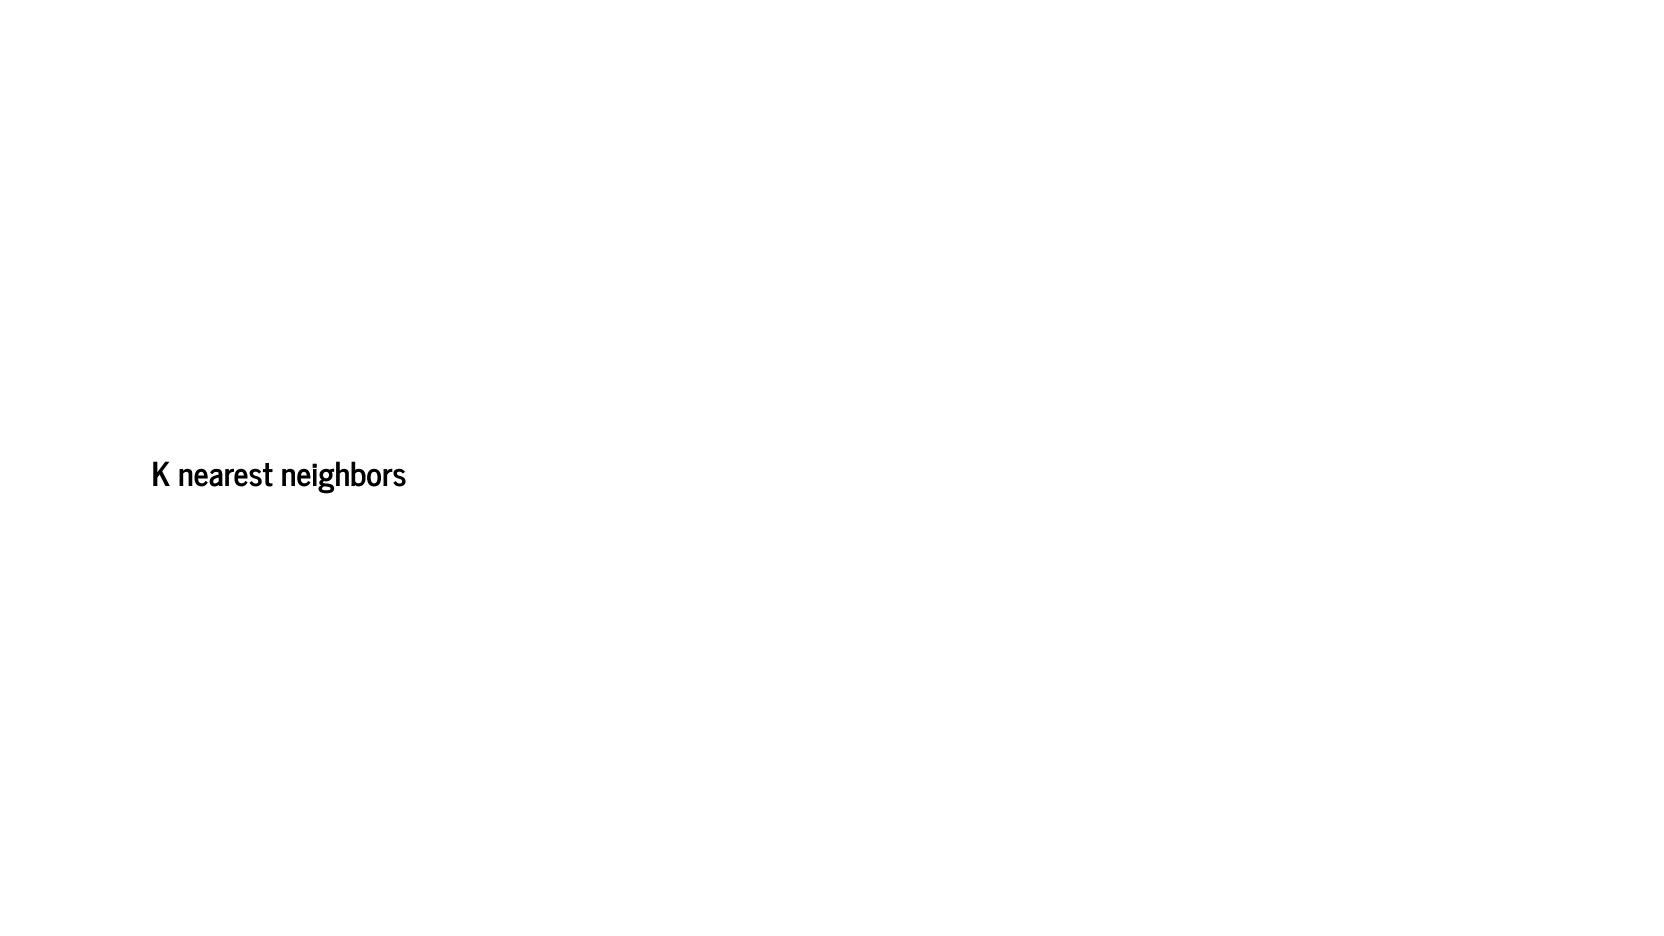

- given a multicolor image of an object through a telescope, determine whether that object is a star, a quasar, or a galaxy.
- given a photograph of a person, identify the person in the photo.
- given a list of movies a person has watched and their personal rating of the movie, recommend a list of movies they would like (So-called *recommender* systems: a famous example is the Netflix Prize (http://en.wikipedia.org/wiki/Netflix\_prize)).

### Supervised learning is further broken down into two categories

- Classification
- Regression

### In classification, the label is discrete, while in regression, the label is continuous

- Classification: Credit card approval/rejection
- Regression: Monthly credit limit

## **About K nearest neighbors** K nearest neighbors (kNN) is one of the simplest learning strategies: given a new, unknown observation, look up in your reference database which ones have the closest features and assign the predominant class.

```
In [1]:
    import pandas as pd
    from sklearn.neighbors import KNeighborsClassifier
    from sklearn.preprocessing import Imputer

    train_url = "https://storage.googleapis.com/kaggle_datasets/Titanic-Machine-Learning-from-Disaster/train.csv"
    train = pd.read_csv(train_url)
    X_train = train[["Fare", "Age"]].values
    imputer = Imputer(strategy="median")
    X_train = imputer.fit_transform(X_train)
    y_train = train["Survived"].values
    knn = KNeighborsClassifier()
    knn.fit(X_train, y_train)
```

KNeighborsClassifier(algorithm='auto', leaf\_size=30, metric='minkowski',

metric params=None, n\_jobs=1, n\_neighbors=5, p=2,

weights='uniform')

Out[1]:

In [2]: test\_url = "https://storage.googleapis.com/kaggle\_datasets/Titanic-Machine-Learning-from-Disaster/test.csv"
test = pd.read\_csv(test\_url)

In [3]: test.head()

Out[3]:

	PassengerId	Pclass	Name	Sex	Age	SibSp	Parch	Ticket	Fare	Cabin	Embarked
0	892	3	Kelly, Mr. James	male	34.5	0	0	330911	7.8292	NaN	Q
1	893	3	Wilkes, Mrs. James (Ellen Needs)	female	47.0	1	0	363272	7.0000	NaN	S
2	894	2	Myles, Mr. Thomas Francis	male	62.0	0	0	240276	9.6875	NaN	Q
3	895	3	Wirz, Mr. Albert	male	27.0	0	0	315154	8.6625	NaN	S
4	896	3	Hirvonen, Mrs. Alexander (Helga E Lindqvist)	female	22.0	1	1	3101298	12.2875	NaN	S

```
In [4]: # How would our current kNN model predict the first passenger with Age=34.5, and Fare=7.8292?
import numpy as np

X_test = np.array([[34.5, 7.8292]]).reshape(1, 2)
knn.predict(X_test)
```

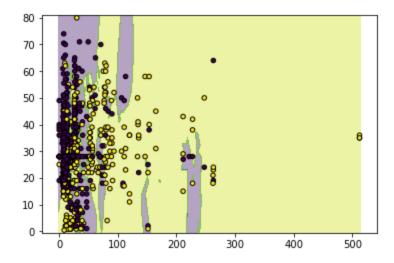

Out[4]: array([0])

We can also do probabilistic predictions:

```
In [5]: knn.predict_proba(X_test)
Out[5]: array([[ 0.6,  0.4]])
```

Let's draw the decision boundary for our current kNN model:

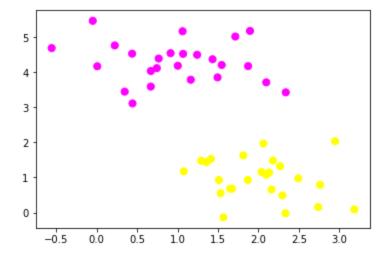

### **About SVM**

Support Vector Machines (SVMs) are a powerful supervised learning algorithm used for **classification**. SVMs are a **discriminative** classifier: that is, they draw a boundary between clusters of data.

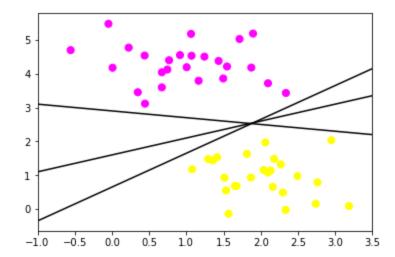

In [9]: plt.show()

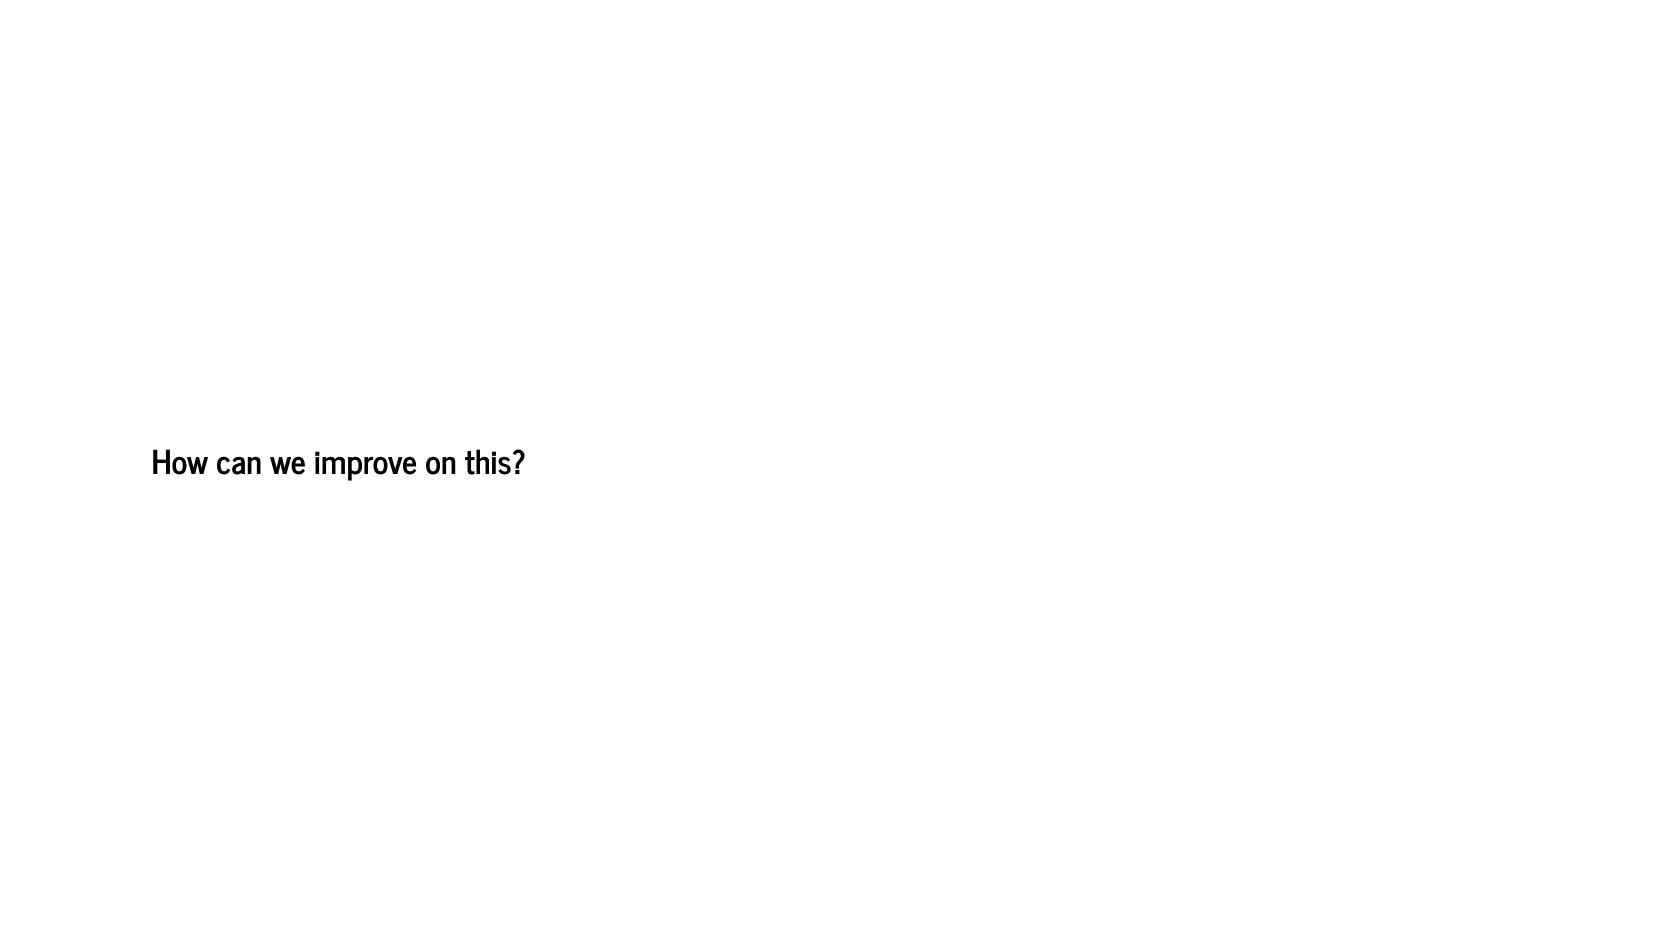

### A discriminative classifier attempts to draw a line between the two sets of data

We could come up with several possibilities which perfectly discriminate between the classes.

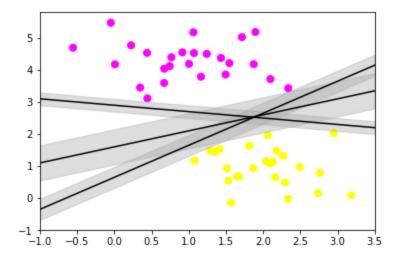

In [11]: plt.show()

Maximizing the <i>Margin</i>
Support vector machines are one way to address this. What support vector machined do is to not only draw a line, but consider a region about the line of some given width.

If we want to maximize this width, the middle fit is clearly t	the best	

### Fitting a Support Vector Machine

tol=0.001, verbose=False)

Out[14]:

Now we'll fit a Support Vector Machine Classifier.

SVC(C=1.0, cache\_size=200, class\_weight=None, coef0=0.0,

decision function shape='ovr', degree=3, gamma='auto', kernel='linear',

max iter=-1, probability=False, random state=None, shrinking=True,

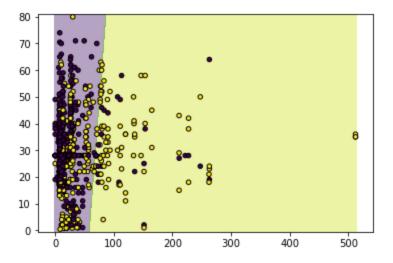

```
In [14]: import pandas as pd
    from sklearn.preprocessing import Imputer
    from sklearn.svm import SVC # "Support Vector Classifier"

    train_url = "https://storage.googleapis.com/kaggle_datasets/Titanic-Machine-Learning-from-Disaster/train.csv"
    train = pd.read_csv(train_url)
    X_train = train[["Fare", "Age"]].values
    imputer = Imputer(strategy="median")
    X_train = imputer.fit_transform(X_train)
    y_train = train["Survived"].values
    svc = SVC(kernel='linear')
    svc.fit(X_train, y_train)
```

### Plot SVM decision boundaries

Out[15]: <matplotlib.collections.PathCollection at 0x1a22acce80>

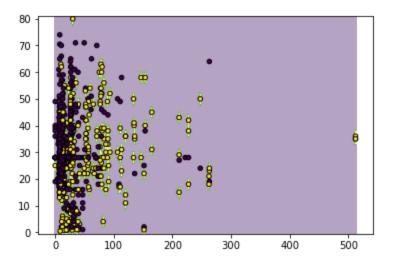

# **Kernel Methods** Where SVM gets incredibly exciting is when it is used in conjunction with kernels, which is some functional transformation of the input data.

```
In [17]: svc = SVC(kernel='rbf')
    svc.fit(X_train, y_train)

# Plotting decision regions
    Z = svc.predict(np.c_[xx.ravel(), yy.ravel()])
    Z = Z.reshape(xx.shape)
    plt.contourf(xx, yy, Z, alpha=0.4)
    plt.scatter(X_train[:, 0], X_train[:, 1], c=y_train, s=20, edgecolor='k')
```

Out[17]: <matplotlib.collections.PathCollection at 0x1a22a64470>

## **About Random Forest** Random forests are an example of an ensemble learner built on decision trees. Decision trees are extremely intuitive ways to classify or label objects: you simply ask a series of questions designed to zero-in on the classification.

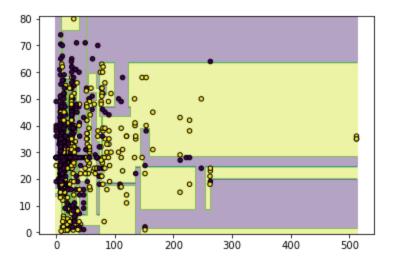

### **Creating a Decision Tree**

```
In [19]: from sklearn.tree import DecisionTreeClassifier

dt = DecisionTreeClassifier()
dt.fit(X_train, y_train)

# Plotting decision regions
Z = dt.predict(np.c_[xx.ravel(), yy.ravel()])
Z = Z.reshape(xx.shape)
plt.contourf(xx, yy, Z, alpha=0.4)
plt.scatter(X_train[:, 0], X_train[:, 1], c=y_train, s=20, edgecolor='k')
Out[19]: 
cmatplotlib.collections.PathCollection at 0x1a2722ff28>
```

In [20]: plt.show()

## **Ensembles of Estimators** An Ensemble Method is a meta-estimator which essentially averages the results of many individual estimators. Somewhat surprisingly, the resulting estimates are much more robust and accurate than the individual estimates which make them up!

### One of the most common ensemble methods

<matplotlib.collections.PathCollection at 0x1a27b0afd0>

Out[21]:

Random Forest, in which the ensemble is made up of many decision trees.

```
In [21]: from sklearn.ensemble import RandomForestClassifier
    forest = RandomForestClassifier(n_estimators=100)
    forest.fit(X_train, y_train)

# Plotting decision regions
    Z = forest.predict(np.c_[xx.ravel(), yy.ravel()])
    Z = Z.reshape(xx.shape)
    plt.contourf(xx, yy, Z, alpha=0.4)
    plt.scatter(X_train[:, 0], X_train[:, 1], c=y_train, s=20, edgecolor='k')
```
